Container network requires base stations

Overview

Network Namespaces: Docker uses Linux network namespaces to create isolated network stacks for each container, ensuring they have their own network interfaces, IP addresses, routing tables, and firewall rules. Containers have networking enabled by default, and they can make outgoing connections. A container has no information about what kind of network it's. Container networking is the fundamental technology that enables communication among containers, the host system, and external networks.

Container network requires base stations

Docker Networking Comprehensive Guide

Docker networking is the system that manages how containers communicate with each other, the host system, and external networks. It provides isolated, virtual networks for containers ...
